Abstract

The slow viscous settling migration of a 2-particle cluster between two solid and parallel plane walls is investigated by resorting to a Boundary Element Method. The procedure, valid for arbitrarily-shaped bodies, is presented and preliminary numerical results for both identical spheres and a spheroid-sphere cluster are discussed. To cite this article: L. Pasol, A. Sellier, C. R. Mecanique 334 (2006).

Résumé

1. Introduction

We look at the slow viscous motion of two interacting solid particles settling in a liquid confined by two solid and parallel plane walls. For such boundaries, available approaches are unfortunately restricted to the case of one sphere [1–3], one particle [4] or two spheres [5] and a new procedure is therefore needed to handle the general case of two arbitrarily-shaped particles. The present Note advocates a fruitful and general treatment that permits us to compute the rigid-body motion of each particle at a reasonable CPU time cost and also gives preliminary results for two sphere–sphere and spheroid-sphere clusters.

2. Governing equations and advocated procedure

As illustrated in Fig. 1, we consider two solid particles \( P_n \) \((n = 1, 2)\) settling under the uniform gravity field \( g \) in a quiescent Newtonian liquid confined by the motionless planes \( \Sigma_1 \) \((x_3 = 0)\) and \( \Sigma_2 \) \((x_3 = H)\) with \( H > 0 \) the large enough gap with between the walls.

Since the arbitrarily-shaped solid \( P_n \) with surface \( S_n \), volume \( V_n \) and mass \( M_n \) is not necessarily homogeneous we denote by \( O_n \) and \( O_n' \) it’s center of volume and center of mass, respectively. Moreover, \( P_n \) experiences with respect to the walls a rigid-body motion with unknown translational velocity \( \mathbf{U}(n) \) \((the velocity of \( O_n \))\) and angular velocity \( \mathbf{\Omega}(n) \) whereas at each point \( M \) in the liquid domain \( \Omega \) the fluid, with uniform viscosity \( \mu \) and density \( \rho \), has velocity \( \mathbf{u} \), pressure \( p + \rho \mathbf{g} \cdot \mathbf{OM} \) and stress tensor \( \mathbf{\sigma} \). Neglecting particles and fluid inertia, \((\mathbf{u}, p)\) is a quasi-static Stokes flow such that

\[
\mu \nabla^2 \mathbf{u} = \nabla p \quad \text{and} \quad \nabla \cdot \mathbf{u} = 0 \quad \text{in} \quad \Omega, \quad (\mathbf{u}, p) \rightarrow (0, 0) \quad \text{as} \quad |\mathbf{OM}| \rightarrow \infty
\]

\[
\mathbf{u} = 0 \quad \text{on} \quad \Sigma = \Sigma_1 \cup \Sigma_2, \quad \mathbf{u} = \mathbf{U}(n) + \mathbf{\Omega}(n) \times \mathbf{OM} \quad \text{on} \quad S_n \quad \text{for} \quad n = 1, 2
\]

Furthermore, on each surface \( S_n \) with unit outward normal \( \mathbf{n} \) the requirement of zero net force and net torque (about \( O_n \)) supplements (1), (2) with the conditions

\[
\mathbf{T}(n) = \int_{S_n} \sigma \cdot \mathbf{n} \, dS_n = (\rho \mathbf{v}_n - M_n) \mathbf{g}, \quad \mathbf{R}(n) = \int_{S_n} \mathbf{O}_n \mathbf{M} \cdot \sigma \cdot \mathbf{n} \, dS_n = -M_n \mathbf{O}_n \mathbf{O}_n' \times \mathbf{O}_n \mathbf{M} \quad \text{on} \quad S_n
\]

Using throughout Cartesian coordinates \((O, x_1, x_2, x_3)\) and the usual tensor summation convention, we obtain the Cartesian velocity components \( U_j^{(n)} = \mathbf{U}^{(n)} \cdot \mathbf{e}_j \) and \( \mathbf{\Omega}_j^{(n)} = \mathbf{\Omega}^{(n)} \times \mathbf{e}_j \) by extending the approach advocated in [6]. For \( n = 1, 2 \) and \( i = 1, 2, 3 \) we thus appeal to 12 Stokes flows \((\mathbf{u}_T(n), i, p_T(n), i)\) and \((\mathbf{u}_R(n), i, p_R(n), i)\) obeying (1) and the boundary conditions

\[
\mathbf{u}_T(n), i = 0 \quad \text{on} \quad \Sigma = \Sigma_1 \cup \Sigma_2, \quad \mathbf{u}_T(n), i = \delta_{nm} \mathbf{e}_i \quad \text{and} \quad \mathbf{u}_R(n), i = \delta_{nm} \mathbf{e}_i \times \mathbf{OM} \quad \text{on} \quad S_m
\]

with \( \delta_{nm} \) the Kronecker delta. For \( L \in \{T, R\} \) the flow \((\mathbf{u}_L(n), i, p_L(n), i)\) has stress tensor \( \sigma_L^{(n), i} \) and exerts on \( S = S_1 \cup S_2 \) the traction \( \mathbf{t}_L^{(n), i} = \mathbf{\sigma}_L^{(n), i} \cdot \mathbf{n} \). Recalling (3) and invoking the usual reciprocal identity [7] with the conditions (4) and \( \mathbf{u} = 0 \) on \( \Sigma \) yields, for \( L \in \{T, R\} \),

\[
\mathbf{L}^{(n), i} \cdot \mathbf{e}_i = \int_{S_n} \mathbf{L}^{(n), i} \cdot \sigma \cdot \mathbf{n} \, dS = \int_{S_1 \cup \Sigma} \mathbf{L}^{(n), i} \cdot \sigma \cdot \mathbf{n} \, dS = \int_{S_1 \cup \Sigma} \mathbf{u} \cdot \mathbf{\sigma}_L^{(n), i} \cdot \mathbf{n} \, dS = \int_{S} \mathbf{u} \cdot \mathbf{f}_L^{(n), i} \, dS
\]

Fig. 1. A two-particle cluster settling between two parallel solid, motionless and plane walls \( \Sigma_1 \) \((x_3 = 0)\) and \( \Sigma_2 \) \((x_3 = H)\) with \( H > 0 \). (a) Side view for two identical spheres. (b) Top view for a sphere and a spheroid.

Fig. 1. Deux particules solides en sédimentation entre deux plans solides fixes et parallèles \( \Sigma_1 \) \((x_3 = 0)\) et \( \Sigma_2 \) \((x_3 = H)\) avec \( H > 0 \). (a) Vue latérale pour deux sphères identiques. (b) Vue de dessus pour une sphère et un ellipsoide de révolution.
Substituting in the right-hand side of (5) the condition (2) for $u$ on $S$ and setting 

$$A_{(m),L}^{(n),i,j} = - \int_{S_m} \mathbf{e}_j \mathbf{f}_L^{(n),i} \, dS_m$$

and 

$$B_{(m),L}^{(n),i,j} = - \int_{S_m} (\mathbf{e}_j \wedge \mathbf{O}_m \mathbf{M}) \mathbf{f}_L^{(n),i} \, dS_m$$

one thus casts (3) into the following 12-equation ($i = 1, 2, 3$ and $n = 1, 2$) linear system

$$\left[ A_{(m),T}^{(n),i,j} U_j^{(m)} + B_{(m),T}^{(n),i,j} \xi_j^{(m)} \right] \mathbf{e}_i = (M_n - \rho \nu_n) \mathbf{g}$$

(7)

$$\left[ A_{(m),R}^{(n),i,j} U_j^{(m)} + B_{(m),R}^{(n),i,j} \xi_j^{(m)} \right] \mathbf{e}_i = -M_n (\mathbf{g} \wedge \mathbf{O}_n^t \mathbf{O}_n)$$

(8)

The real-valued matrix of the above system is symmetric by virtue of the reciprocal identity (use (6)) and also found to be positive-definite by extending the proof established in [6] for a single wall. Thus, (7), (8) admits a unique solution

$$\mathbf{U}^t = \mathbf{O}_n \mathbf{u}$$

(9)

and

$$\mathbf{R} = \mathbf{O}_n \mathbf{0}$$

(10)

with $\delta_n$ the Dirac pseudo-function. Not only because both $\mathbf{u}_L^{(n),i}$ and $\mathbf{T}_j$ vanish on the walls $\Sigma_1$ and $\Sigma_2$ but also since $\mathbf{u}_L^{(n),i}$ turns out to be a rigid-body motion on each surface $S_1$ and $S_2$, one deduces [8] the following Fredholm boundary-integral equations of the first kind

$$\left[ \mathbf{u}_L^{(n),i} \mathbf{e}_j \right] (M) = - \int_S T_{jk} (M, P) \left[ \mathbf{f}_L^{(n),i} (P) \mathbf{e}_k \right] \, dS_P$$

(11)

In summary, the motion of the two-particle cluster is determined as follows:

(i) First, we obtain the tractions $\mathbf{T}_{jk}^{(n),i}$ by solving 12 boundary-integral equations (11) for $L = T, R; n = 1, 2$ and $i = 1, 2, 3$.

(ii) We subsequently calculate the quantities $A_{(m),L}^{(n),i,j} \mathbf{e}_j$ and $B_{(m),L}^{(n),i,j} \mathbf{e}_j$ and solve the linear system (7), (8) to obtain the rigid-body motions $(\mathbf{U}^{(1)}, \mathbf{O}^{(1)})$ and $(\mathbf{U}^{(2)}, \mathbf{O}^{(2)})$.

3. Numerical implementation

The weakly-singular integral equation (11) is treated by splitting $T_{jk}$ into singular and regular terms. More precisely, one obtains the decomposition

$$T_{jk} (M, P) = \frac{1}{8 \pi J_k} \left[ G_{jk} (M, P) + R_{jk} (M, P) \right], \quad G_{jk} (M, P) = \frac{\delta_{jk}}{PM} + \frac{[\mathbf{PM} \mathbf{e}_j][\mathbf{PM} \mathbf{e}_k]}{PM^3}$$

(12)

with $G_{jk}$ the usual stokeslet component [8] prevailing in absence of boundaries and $R_{jk}$ a regular function independent of $\mu$. Very or rather cumbersome formulae are available for $R_{jk}$ in [9] or [3], respectively. The present work appeals to the results given in [3] which, however, are unfortunately too long to be reproduced here. The decomposition (12) yields an accurate numerical discretization of (11) by using 6-node curved triangular and isoparametric boundary elements [10] on $S$. For a $N_n$-node mesh on $S_n$ Eq. (11) thus becomes a $3(N_1 + N_2)$-equation linear system which is solved by Gaussian elimination.

4. Results and discussion

To our very best knowledge, only [5] copes with two particles between two plane walls. Moreover, [5] rests on a quite different multipole approach restricted by essence to spherical bodies and gives accurate numerical results...
Table 1
Comptes de coefficients $c_i^{(1)}$ et $c_i^{(2)}$ en utilisant des maillages de maillages à une valeur très proche ($\lambda = 1.1$) ou proches ($\lambda = 2$) de $N_n$-node meshes for each $S_n$ for either very close ($\lambda = 1.1$) or close ($\lambda = 2$) and surfaces adjacent to $N_n$ noed on each surface $S_n$ are utilised.

only for two equal spheres $P_n$, with center $O_n$, radius $a$, $H = 4a$ and such that $OO_1e_3 = OO_2e_3 = 2a$. For such a geometry, sketched in Fig. 1(a), [5] actually provides (with no summation over indices $i$ in (13)) the coefficients

$$c_i^{(n)} = -A_{i,j}^{(1)}t_i/(6\pi a\mu)$$

(13)

for a few values of the sphere–sphere separation parameter $\lambda = O_1O_2/2a > 1$. Our method is benchmarked in Table 1 against these results either for very close ($\lambda = 1.1$) or close ($\lambda = 2$) spheres and several $N_n$-node meshes on $S_n$ with $N_1 = N_2$.

It clearly appears that using 242 nodes on each sphere ascertains a quite sufficient relative accuracy of order of one percent for the selected sphere–sphere gaps. We thus take $N_1 = N_2 = 242$ in investigating the settling of this cluster for the small gap with $H = 2.4a$ and spheres having the same uniform density $\rho_s$. Symmetries show that if $g = ge_3 \neq 0$ the velocity components

$$u_{i,j}^{(n)} = 9\mu U_{i,j}/[2a^2(\rho_s - \rho)g]$$

and

$$w_{i,j}^{(n)} = 9\mu \Omega_{i,j}/[2a^3(\rho_s - \rho)g].$$

(14)

here normalized by the settling velocity of a single sphere, are zero except $u_i = u_{i,i}^{(1)} = u_{i,i}^{(2)}$ for $i = 1, 2, 3$; $w_2 = w_{2,2}^{(1)} = -w_{2,2}^{(2)}$ ($i = 2$) and $w_3 = w_{3,2}^{(1)} = -w_{3,2}^{(2)}$ ($i = 3$). These quantities are plotted in Fig. 2 versus the sphere–sphere separation $\lambda$ in absence of walls, for a single wall $\Sigma_1$ and for both walls $\Sigma_1$ and $\Sigma_2$.

By symmetry, the walls induce interactions of equal magnitude which, as seen in Fig. 2, preserve the hierarchy $u_1 > u_2 > u_3$, $w_3 > -w_2$ observed for a single wall and slow down the cluster more but not twice more than in this latter case. As for a single wall, each velocity tends to its asymptote faster than in absence of walls and $u_1$, $w_3$, $-w_2$ increase as spheres approach whereas $u_3$ is nearly constant, i.e., spheres ignore each other for $g = ge_3$. By contrast, as $\lambda$ increases $u_2$ monotonically decreases for a single wall but first decreases and then slowly increases for our close walls ($H = 2.4a$). Thus, for $OO_1e_3 = 1.2a$ and $\Sigma_2 (x_3 = H)$ with $H \geq 2.4a$ there exists a critical spacing $e_3$ at which $u_2(\lambda, e_3) = u_2(\infty)$ with each sphere ignoring the other one.

Contrary to the multipole method [5], the present approach can deal with non-spherical particles. We illustrate this point by replacing the sphere $P_1$ of the previous 2-sphere cluster with a prolate spheroid having, as depicted in Fig. 1(b), center $O_1$ with $O_1O_2$ parallel to $e_1$, and semiaxes $b$ in the directions $e_1$ or $e_3$ and $c > b$ in the direction $e_2$. Looking at the sensitivity of both wall–particle and particle–particle interactions to the shapes of the bodies, we require the spheroid and the sphere to be equivalent when isolated, i.e., to experience the same settling velocity $U_s = 2a^2(\rho_s - \rho)g/9$ for $H \to \infty$ and $O_1O_2 \to \infty$. If $P_1$ has the uniform density $\rho_s$ and a prescribed ratio $t = c/b$ this occurs for $g = ge_3 = 0$ if (see [7])

$$b = a\left\{\frac{3}{8}\left[\frac{t^2}{t^2 - 1} + \frac{2t^3 - 3t}{(t^2 - 1)^{3/2}} \log(t + \sqrt{t^2 - 1})\right]\right\}^{-1/2}$$

(15)

We select $t = 3/2$, thus arriving at $b \sim 0.89a$ and $c \sim 1.34a$, and plot in Fig. 3 the non-zero normalized velocities $u_{1,1}^{(n)}$, $u_{3,3}^{(n)}$ and $w_{3,2}^{(n)}$ versus the new separation parameter $\lambda = O_1O_2/(a + b) > 1$ for strong wall–particle interactions with $H = 2.4a$. 

---

Fig. 2. Non-zero normalized translational and angular velocities for two identical spheres. (a) $u_1$ (solid curve) and $u_2 = u_3$ (dashed curve) in absence of walls; $u_1$ ($\circ$), $u_2$ ($\square$) and $u_3$ ($\triangle$) for a single wall $\Sigma_1$; $u_1$ ($\bullet$), $u_2$ ($\blacksquare$) and $u_3$ ($\blacktriangle$) for two walls $\Sigma_1$ and $\Sigma_2$. (b) $w_3 = -w_2$ (solid curve) in absence of walls; $w_2$ ($\square$) and $w_3$ ($\circ$) for a single wall $\Sigma_1$; $w_2$ ($\blacksquare$) and $w_3$ ($\blacktriangle$) for two walls $\Sigma_1$ and $\Sigma_2$.

Fig. 3. Non-zero normalized velocities for a settling spheroid–sphere cluster. (a) Spheroid velocity $u^{(1)}_{1,1}$ ($\bigcirc$) and sphere velocity $u^{(1)}_{1,1}$ ($\bullet$) for $g$ parallel to $e_1$ with $u^{(2)}_{1,1}$ for the 2-sphere cluster recalled by the solid curve. (b) Spheroid velocity $u^{(1)}_{3,3}$ ($\bigcirc$) and sphere velocity $u^{(2)}_{3,3}$ ($\bigstar$) for $g$ parallel to $e_3$ with $u^{(2)}_{3,3}$ ($\bigstar$) for the 2-sphere cluster. (c) Quantities $10^3 u^{(1)}_{3,2}$ ($\bullet$) for the spheroid and $-10^3 w^{(2)}_{3,2}$ ($\circ$) for the sphere if $g$ is parallel to $e_3$ with the values of $10^3 u^{(1)}_{3,2} = -10^3 w^{(2)}_{3,2}$ ($\bigstar$) for the 2-sphere cluster.

As seen in Fig. 3(a), the sphere settles faster than the spheroid if $g$ is parallel to $e_1$ and the spheroid or the sphere translates slower or faster, respectively, than the 2-sphere cluster. In addition, the velocity of the 2-sphere cluster
tends to the velocity of the spheroid or the velocity of the sphere for close or distant spheroid and sphere, respectively. Fig. 3(b) reveals that, by contrast, the spheroid settles normal to the walls faster than the sphere (for distant particles, this agrees with a lubrication theory relevant for the addressed small wall–sphere and wall–spheroid gaps). In addition, the 2-sphere cluster moves this time faster than the sphere and slower than the spheroid even for very close particles. Finally, the spheroid and the sphere rotate, with $\Omega(n)$ parallel to $e_2$, only when $g$ is normal to the walls. As observed in Fig. 3(c), the sphere is found to rotate faster than the spheroid, except for very close particles ($\lambda \lesssim 1.2$).

5. Concluding remarks

Because (11) actually also holds in the entire fluid domain, the proposed procedure makes it possible to compute, if necessary, the velocity field $u$ in the liquid. Finally, it should be outlined that our treatment is likely to be extended to the challenging case of clusters involving more than two arbitrarily-shaped and strongly interacting particles confined between two parallel solid plane walls. This basic issue however requires a substantial additional analysis which is therefore postponed to a future work.
